

Calculating Exponential Growth

Formula for Exponential Growth

A quantity A that has exponential growth can be modeled by

$$A = P(1 + r)^n$$

A measures the quantity at any time.

P is the initial value of A, when $n = 0$.

r is the rate (%) of growth, in decimal form.

n is the elapsed time.

<http://www.math.andyou.com/152>

IN OR Y^x → decimal

EXAMPLE: The growth rate of a bacteria culture is 52% each hour. Initially, there are two bacteria. How many bacteria are there after 12 hours?

A = ?
 P = 2
 r = 0.52
 n = 12

$$A = P(1 + r)^n$$

$$A = 2(1 + 0.52)^{12}$$

A = 304 bacteria

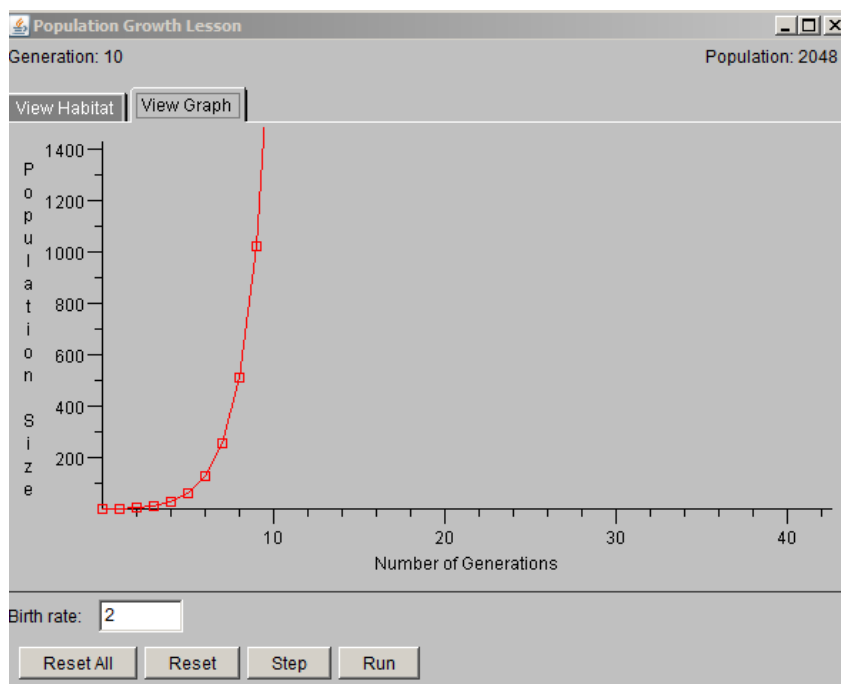

SOLUTION

Under ideal conditions:

NOTES - Exponential Growth.pdf

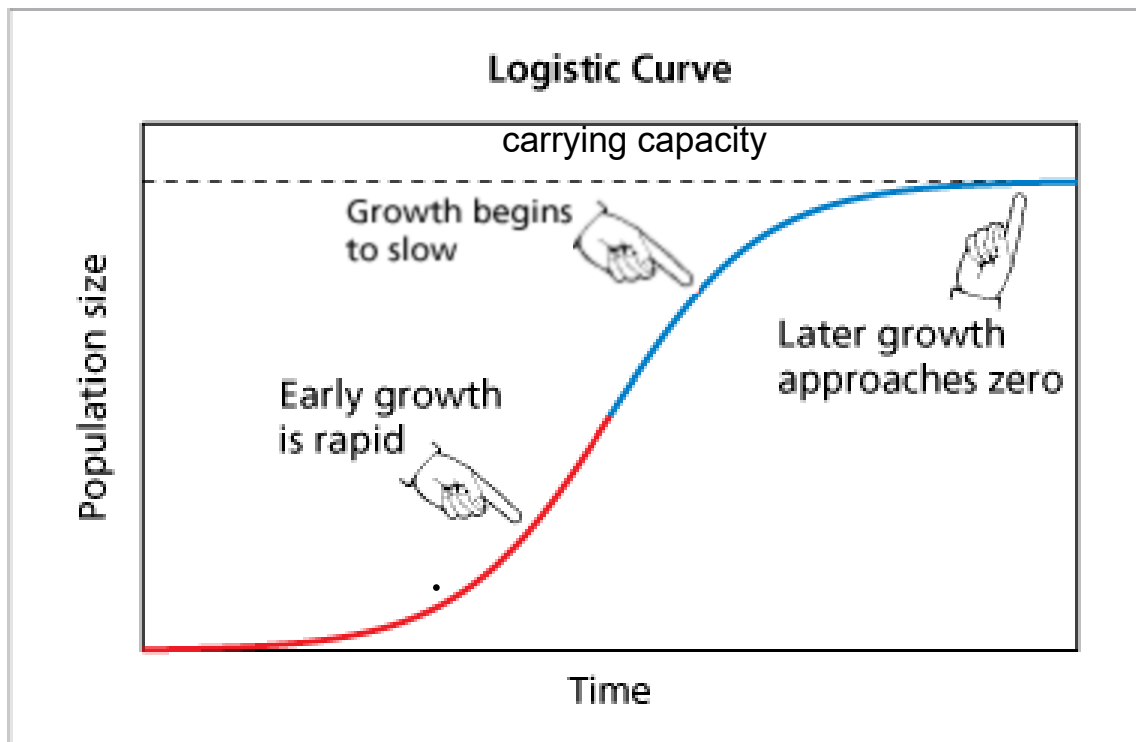

1. the **biotic potential** of a population is the maximum rate at which it can increase
2. **exponential growth** occurs - the population increases by the same percent from one time period to the next.

<http://www.otherwise.com/population/exponent.html>

- In nature, there are always limits to growth. A population will reach a size limit imposed by a shortage of one or more of the **limiting factors** of light, water, space and nutrients.
- **Carrying capacity** represents the highest population that can be maintained for an indefinite period of time by a particular environment.
- When a population grows exponentially at first, and then levels off to a stable number near the carrying capacity, it is called **logistic growth**. Logistic growth is much more common in nature than long-term exponential growth.
- **Natural Capital** - refers to all the natural resources on which people depend upon and includes resources we use to produce manufactured goods.

Exponential Growth -> "J"Curve
 Logistic Growth -> "S" curve
